

Warehouse Order Processing System

Develop a small Python-based order processing system for an e-commerce warehouse.

When an order is received, the warehouse needs to capture basic order information and determine how the order should be processed.

Your solution should be able to:

1. Accept the required information from the user.
2. Perform the necessary calculations.
3. Apply all relevant business rules correctly.
4. Display a meaningful order-processing summary.

The system should collect the following information:

- Customer ID
- Order value
- Number of items
- Delivery distance in kilometres
- Whether the customer is a premium member
- Whether the order requires priority processing
- Whether the order contains a fragile item

Calculate Shipping cost: The system should then calculate the shipping cost using the following rule: Shipping cost = ₹50 base charge + ₹8 for every kilometre of delivery distance.

The warehouse follows these business rules:

- An order can be processed only when its value is greater than ₹500, it contains at least one item, and the delivery distance does not exceed 100 km.
- Customers receive free shipping when the order value is at least ₹2,000 or the customer is a premium member.
- An order receives priority processing only when it is marked as a priority order and its value is at least ₹1,500.
- An order requires special handling when it contains a fragile item or contains 10 or more items.

After processing the order, display a clear summary showing the customer, order details, calculated values, order status, shipping status, processing priority, and handling requirements.

Example Order

For an order such as:

Customer ID: C104
Order value: 2450
Number of items: 6
Delivery distance: 18
Premium member: Yes
Priority order: No
Fragile item: Yes

Output should be:

```
=====
                        ORDER PROCESSING RESULT
=====
Customer      : C104
Order value   : ₹2450
Items         : 6
Distance      : 18 km

Status        : ACCEPTED
Shipping      : FREE
Processing    : STANDARD
Handling      : SPECIAL
=====
```
